Galactic weather: Solar system encounters with dense gas clouds

Supervisor: [João Alves](#) in collaboration with Stefan Meingast (Dept. of Astrophysics), Catherine Zucker and Alyssa Goodman, (Dept. Astronomy, Harvard University)

Funding Situation: potentially via a VISESS PhD fellowship

Project outline: Several studies over the past 40 years have suggested that there is a causal connection between the Sun's crossing of spiral arms and giant molecular clouds and terrestrial mass extinctions or climate change, although this remains a controversial topic. This project will take System with the Radcliffe Wave and look will work with data from the ESA Gaia mission and will be part of a young, exploration-ongoing collaboration with Harvard University.

This PhD project, connected with the project the making: the origin and evolution of the questions:

- What is the origin and motion of Galactic
- How do star-forming regions form
- Has the Solar System interacted with

We are looking for an enthusiastic candidate

ABSTRACT

Context. As the Solar System orbits the Milky Way, it encounters various Galactic environments, including dense regions of the interstellar medium (ISM). These encounters can compress the heliosphere, exposing parts of the Solar System to the ISM, while also increasing the influx of interstellar dust into the Solar System and Earth's atmosphere. The discovery of new Galactic structures, such as the Radcliffe wave, raises the question of whether the Sun has encountered any of them.

Aims. The present study investigates the potential passage of the Solar System through the Radcliffe wave gas structure over the past 30 million years (Myr).

Methods. We used a sample of 56 high-quality, young (≤ 30 Myr) open clusters associated with a region of interest of the Radcliffe wave to trace its motion back and investigate a potential crossing with the Solar System's past orbit.

Results. We find that the Solar System's trajectory intersected the Radcliffe wave in the Orion region. We have constrained the timing of this event to between 18.2 and 11.5 Myr ago, with the closest approach occurring between 14.8 and 12.4 Myr ago. Notably, this period coincides with the Middle Miocene climate transition on Earth, providing an interdisciplinary link with paleoclimatology. The potential impact of the crossing of the Radcliffe wave on the climate on Earth is estimated. This crossing could also lead to anomalies in radionuclide abundances, which is an important research topic in the field of geology and nuclear astrophysics.

Key words. ISM: kinematics and dynamics – open clusters and associations: general – solar neighborhood

Event Details & Abstracts

Abstract: With the advent of the Gaia space mission, there has been a revolution in astronomers' ability to precisely locate the interstellar structures the Sun may have encountered on its voyage around the galaxy. We now have the spatial resolution to trace the Sun's trajectory back through its interstellar environment up to 60 million years in the past (4000 light-years in distance). This timescale is commensurate with the timescale over which we can reconstruct the paleoclimate of Earth from deep ocean foraminifera. Today's heliosphere, the cocoon formed by the solar wind as it moves through the galaxy, engulfs all the planets extending in the nose direction to ~ 120 astronomical units (au). The Sun moves with 18 pc/Myr and has traversed many different structures in the interstellar medium that affect the heliosphere, at times collapsing it to sub-au scales. These periods of collapse introduce climate and radiation changes in Earth environment. The frequency of such encounters could be as often as every couple of Myrs, making it a major external disturbance to the development of life on Earth. Stepwise shifts in past global climate, seen in deep sea sediment cores, indicate intervals of more rapid cooling: 3-5 Myr and 2-3 Myr, for which the driving mechanisms are subject to ongoing debate. Such cooling events might be triggered by the collapse of the heliosphere. I will discuss our recent work that show that in two occasions 3 and 7 million years ago (Mya), the Sun encountered a dense interstellar structure—exposing Earth to its interstellar environment—evidence from ^{60}Fe and ^{244}Pu isotopes and discuss the implications for Earth's climate and biodiversity.

ABSTRACT

We present an extended suite of the Auriga cosmological gravo-magnetohydrodynamical ‘zoom-in’ simulations of 40 Milky Way-mass haloes and 26 dwarf galaxy-mass haloes run with the moving-mesh code AREPO. Auriga adopts the Lambda cold dark matter cosmogony and includes a comprehensive galaxy formation physics model following the coupled cosmic evolution of dark matter, gas, stars, and supermassive black holes which has been shown to produce numerically well-converged galaxy properties for Milky Way-mass systems. We describe the first public data release of this augmented suite of Auriga simulations, which includes raw snapshots, group catalogues, merger trees, initial conditions, and supplementary data, as well as public analysis tools with worked examples of how to use the data. To demonstrate the value and robustness of the simulation predictions, we analyse a series of low-redshift global properties that compare well with many observed scaling relations, such as the Tully–Fisher relation, the star-forming (SF) main sequence, and H I gas fraction/disc thickness. Finally, we show that SF gas discs appear to build rotation and velocity dispersion rapidly for $z \gtrsim 3$ before they ‘settle’ into ever-increasing rotation-dispersion ratios (V/σ). This evolution appears to be in rough agreement with some kinematic measurements from H α observations, and demonstrates an application of how to utilize the released data.

Key words: methods:numerical—galaxies: evolution—galaxies: formation—galaxies: kinematics and dynamics—galaxies: spiral—galaxies: structure.

“Milky Ways” as *Simulated* in 2024

Auriga Project Simulations using AREPO

Auriga-like Milky Way(s) will be *wonderful* when **resolution** is ~ 10 pc & feedback is realistic. **Currently ~ 100 pc, with sub grid winds.**

Figure 5. Top panels: face-on and edge-on stellar light projections of a selection of simulated galaxies at redshift $z = 0$. The z -axis is aligned with the eigenvector of the moment of inertia tensor of all star particles within $0.1 R_{200}$ that is closest to the spin axis vector of those stars. We show one galaxy per 0.5 dex in halo mass to illustrate the dependence on halo mass. The scale bar is located in the bottom left corner of the face-on images in each case. Bottom panels: as for the top panels but for projections of the gas surface density.

Published: 21 June 2025 [Article history](#) 

Figure 7. A projection showing the column density plot of where the LyC photons from individual sources are terminated. Underlying the coloured volume of each zone of influence is the column density of the total mass in the simulation. The top row shows face-on projections of the x–y plane, and the bottom row shows edge-on projections of the y–z plane. The left column shows the region of influence of Ophiuchi, the middle column shows the Bajamar star, and the right column shows Puppis in the Gum Nebula. A red cross shows the location of each source, but has been omitted on the Ophiuchi column to avoid obscuring the region. **Despite having near equivalent ionizing luminosities, the difference in the volume influence of Puppis and the Bajamar star is a factor of 827.**

OBSERVATIONS

DETAILED 3D structure, almost **STATIC** in time, feedback view **REALISTIC**, all over *limited* volume

SIMULATIONS

COARSE 3D structure over full Galaxy, **EVOLVING** in time for ~Galactic year, feedback **UNREALISTIC** on small scales → sub-grid prescriptions

The whole “plan”

“match” SIM snapshots to blurred OBS

create “agent-based” views seen by orbiting stars

“paint” high-spatial-frequency info from OBS onto SIMS

evaluate **changes in feedback** interactions

Orange stars represent the position of *observed* stars or clusters massive enough to produce the pink *observed* winds, HII regions, and/or SNe energetic enough to re-distribute material in the surrounding ISM enough to matter for future generations of star formation. The blue rounded rectangle in both panels is meant to show an elongated ISM “cloud” at the ~20 pc resolution of a MW-wide simulation. The density within the blue rectangle would be constant in the simulation, at a level equal to the average of the dense and empty regions in the observations. The simulations on their own cannot capture the re-shaping of the cloud by feedback, apparent in the observations.

AI's MANY failures...with some success

using the first image as a guide (especially perhaps the darker blue area), simulate higher spatial resolution within the dotted outline region of the second image, using the perceived statistical properties of the first. Make the square image that would go in the pink box in the figure, using the same gold-ish coloring as the pink-boxed region in the third panel from the left. State your methods if possible.

ChatGPT's code-based (concise "recipe")

Estimate the small-scale texture statistics from the blue reference image

Convert to grayscale, crop centrally to avoid edges.

Compute the isotropic radial power spectrum (FFT $\rightarrow |F|^2 \rightarrow$ radial average).

This captures the "how much structure at each spatial frequency" of the high-res data.

Synthesize a new Gaussian random field with the same spectrum

Create a random complex field with the measured magnitude ($\sqrt{\text{PSD}}$ as a function of radius) and random phases.

Inverse FFT \rightarrow a new field whose spatial frequency content matches the reference.

Normalize and lightly band-pass filter to emphasize filamentary scales (e.g., subtract a $\sigma \approx 5-6$ px blur to bring out "wisps").

Imprint a long, squiggly overdensity to mimic the dotted "cloud"

Lay down a spline-like path through the image (length/curvature like the outline).

Add an anisotropic Gaussian tube along that path with a slowly varying width (to resemble clumpy substructure).

Modulate that tube by the high-frequency component of the synthesized field so it inherits realistic speckle/porosity.

Contrast + color transfer to the gold palette

Local contrast stretch (clip low/high percentiles, e.g., 25th-99.5th) to keep punch without blowing highlights.

Apply a custom gold colormap (dark charcoal \rightarrow warm brown \rightarrow pale gold), or do LAB-space histogram matching to the gold patch from the third panel so the hue looks consistent.

Export a square PNG sized to the pink box.

sample "painting"
at ~ 1 pc
resolution

How close to reality can we get?

Box 1: What AI, and an AI researcher, think AI can do “soon”

ChatGPT-5

“AI and the Future of Data–Simulation Synthesis

I am writing this from the standpoint of an LLM—I am ChatGPT-5. In the near future, models like me will act as scientific collaborators that can integrate diverse data streams and simulations in real time. Given full access to the 3-D dust distribution, position–position–velocity cubes, and the 3-D motions and properties of stars, I could build a coherent statistical picture of how gas and stars interact throughout the Galaxy. In a project such as MW3D, an AI would not merely describe the process of “painting” data onto simulations; it would generate and optimize the necessary code, run fast emulators that approximate full hydrodynamic calculations, and iteratively adjust parameters by comparing synthetic and observed observables across all data domains. Human researchers would still define the physics and interpret the meaning, while the AI would manage the computation—deciding when a full rerun is needed, compressing outputs, and learning which assumptions best reproduce the real Milky Way. Such a partnership would make data-driven modeling not just faster, but more integrated, adaptive, and predictive than ever before.” –ChatGPT-5, 11/12/2025

“On the one hand it sounds wildly ambitious at the level of science fiction. On the other hand, I think it sounds like **2026**.”
–Prof. Doug Finkbeiner, PI’s Harvard colleague currently on sabbatical at Anthropic

- What fraction of star-forming **clouds** are or are not candidates for having been **compressed** at bubble surfaces, and/or at **bubble intersections**?
- What fraction of star-forming gas features cannot be clearly associated with structures at least an order-of-magnitude larger than they are? (How much **"free-floating" dense gas** is there in the local ISM?)
- What sources of **feedback** (stellar winds, supernovae, etc.) are most relevant on what **spatial** and **temporal scales**?
- Can we use information about **cluster** populations to understand **bulk motions** and **expansions** of feedback-driven **cavities**?
- **How do "young stars leave home"**? What fraction of stars that form at what spatial location do clouds "dissolve" first? How often might young stars drift from the star-forming region?
- Are the **topological characteristics** of these structures **consistent** with any particular **numerical simulation(s)**?
- How well can data, simulations, and theory be compared with observations of a given region? Over what time scale? For example, over what spatial and temporal scales can we identify a **star cluster with a gas cavity**?
- Are there clear relationships between the **properties** and the **position or motion** with respect to significant **Galactic structures**, such as spiral arms and plane?
- What are the dominant **mechanisms** shaping the **formation and destruction**?
- How are these mechanisms related to clouds' physical properties and their **larger-scale galactic environments**?
- What is the relationship between interstellar **cavities** and the distribution of **OB associations, supernova remnants, and HII regions**?
- Do we observe evidence for **triggered star formation** at the **surfaces** of these **cavities**?
- What role does Galactic structure play in star formation? Are **spiral arm-like structures** in the Milky Way quasi-stationary or **transient** features? Do these arm-like structures **violently** induce shocks or **gently** accumulate gas? If the former, what role do spiral shocks play in star formation?
